(54) Title: ABNORMALITIES DETECTION WITH ACOUSTIC MONITOR**(57) Abstract**

Monitor for detecting abnormalities and thus determining the operating condition thereof by continuously computing the power spectrum of the monitored sound and has two modes of operation: learn and operate. The monitor is placed in the learn mode during a time when the machine or process to be monitored is known to be operating normally. During the learn mode, the maximum and minimum acoustic power output from each of a plurality of digital bandpass filters is continuously maintained and updated in data memory as the acoustic signature of the machine or process being monitored. During the operate mode, the monitor continuously compares the real-time filter outputs with the acoustic signature stored during the learn mode and activates a panel lamp and relay if the output of any of the bandpass filters deviates from the upper or lower decibel limits of the acoustic signature by more than the setting of the corresponding front panel sensitivity selector switch. Two alarm levels are provided by the monitor: warning, to indicate a developing fault, and danger, to indicate a situation requiring immediate corrective action.

1 ABNORMALITIES DETECTION WITH ACOUSTIC MONITOR

FIELD OF THE INVENTION

This invention generally relates to the field of monitoring a sound source for determining its operating condition, particularly relates to the fields of machinery condition monitoring, acoustics, and digital signal processing, and specifically relates to the real-time digital filtering of an acoustical signal to obtain its power spectrum, and the comparison of the power spectrum with a previously determined baseline spectrum as a means of detecting developing machinery faults.

BACKGROUND OF THE INVENTION

There has been commercial activity in the field of machinery condition monitoring for at least 25 years, almost all of it based on either periodic or continuous measurement of machine vibration. Acoustic monitoring has rarely been used for detecting machinery faults, even though sound and vibration are closely related. A rotating or reciprocating machine, for example, produces dynamic forces (forces which are rapidly changing functions of time) which cause various parts of the machine to vibrate. These vibrations also cause sound to be radiated from the machine. The relationship between the dynamic forces acting within a machine and the sound radiating from the machine is complex. The vibration spectrum (the displacement amplitude as a function of frequency) depends on the measurement location on the machine, as well as the orientation of the vibration transducer with respect to the axis of rotation of the machine. The sound spectrum (the acoustic power as a function of frequency) depends on the orientation of the microphone with respect to the machine, the directional characteristics of the microphone, and the acoustical characteristics of the surrounding objects and structures. The point of origin of a vibration component may not be an efficient radiator of sound; nevertheless, it is still possible to hear this vibration component if it is transmitted to another part of the machine which is

-2-

1 mechanically resonant at that frequency. The design of the machine, and especially the damping characteristics of the materials used, greatly affects the intensity and spectral distribution of the radiated sound.

5 A machine which is in good condition and functioning properly will have a certain vibration spectrum, which in turn will generate a certain sound spectrum, that is, an acoustic signature which can be used as a reference or baseline. In general, the vibration spectrum and the sound
10 spectrum are not the same; in fact, they may be quite different. But, if the condition of the machine deteriorates, or if there is a sudden failure, the vibration spectrum, and therefore the sound spectrum, will change. The deteriorating machine condition can be detected by
15 continuously monitoring the sound coming from the machine, computing the power spectrum, and comparing the power spectrum to the baseline spectrum stored in memory. If the real-time power spectrum deviates from the baseline spectrum by more than a predetermined amount, an alarm can be
20 activated, along with automatic shutdown of the monitored machine, if desired.

There are many types of machine faults that could be detected by such a monitor; for example, rotating imbalance, reciprocating imbalance, misaligned or bent shafts, damaged
25 rolling element bearings, damaged journal bearings, damaged or worn gears, broken drive belts or chains, mechanical looseness, jamming, overloading, friction, windage, impacts, explosions, and escaping air, water, or steam. An acoustic monitor could also provide protection for non-rotating
30 equipment such as boilers, electrical transformers, and flow processes.

The art and science of vibration-based machinery condition monitoring is highly developed, and there are many commercially available products for measuring vibration, and
35 for collecting, storing, analyzing, and displaying vibration data. In recent years, there has been a significant increase in activity in this field because of the widespread

-3-

1 availability of digital signal processing (DSP) hardware .
such as DSP microcomputers. These are high speed
single-chip computers which incorporate a high degree of
operational parallelism and which are designed to implement
5 computationally intense DSP algorithms such as the fast
Fourier transform (FFT), widely used to compute the power
spectrum of a vibration signal. Vibration analysis
techniques have been developed to detect and diagnose
specific machine faults, using commercially available
10 hardware and software tools. The usual approach is to
measure vibration with an accelerometer which is in direct
contact with the machine being monitored or studied, and
then process the resulting signal with an instrument known
as a dynamic signal analyzer (DSA). This equipment is
15 expensive, the placement and orientation of accelerometers
on the machine can be critical, and skilled personnel are
required to operate the DSA and correctly interpret the
resulting vibration spectra.

With regard to the early detection of machinery
20 problems, in many cases the first indication of trouble is
the sound that a machine makes. In fact, it may be argued
that acoustic monitoring (by human observers) is the oldest
form of machinery condition monitoring in existence.
Experienced machine operators or plant maintenance personnel
25 can often recognize that a machine is in distress because
they are familiar with what the machine sounds like when it
is operating normally. An acoustic monitor could, in
effect, replace human observers in situations where
machinery is operating in remote, inaccessible, or hazardous
30 locations, or any other situation where machinery requires
continuous monitoring. The acoustic monitor according to
the teachings of the present invention is intended to be
affordable, dependable, easy-to-use, and easy-to-install and
has, as its purpose, machinery protection rather than
35 machinery fault diagnosis or testing. Once the user has
been alerted to the fact that machinery is in distress, more
sophisticated equipment can be used to diagnose the specific

-4-

1 problem. It is not necessary to continuously monitor the
machinery with costly vibration-based instrumentation.

DESCRIPTION OF THE PRIOR ART

At the present time, there is only one commercially
5 available product known to be capable of continuous acoustic
monitoring of industrial processes and equipment: the Model
261 Sound Level Detector/Controller, manufactured by Quest
Electronics of Oconomowoc, Wisconsin. This product is
essentially a sound level measuring instrument with an
10 output relay having an adjustable threshold calibrated in
decibels (dB). It measures the root-mean-square (RMS) sound
pressure level (SPL) sensed by a microphone and actuates a
relay if the threshold setting is exceeded. Other than
providing the A and C frequency weighting commonly used for
15 sound level measurements, this product does not perform any
type of filtering or spectral analysis. It is a broadband
instrument which simply measures the combined effect of all
the frequency components of a signal. Primarily intended
for industrial hygiene purposes (noise control and warning),
20 it can also be used to provide an alarm signal or
automatically shut down a machine if the sound pressure
level exceeds the threshold setting.

SUMMARY OF THE INVENTION

An acoustic monitor according to the teachings of the
25 present invention is a self-contained system which detects
faults in the operating condition by continuously analyzing
the sound produced by the sound source being monitored and
comparing the resulting power spectrum to a previously
recorded "acoustic signature" used as a baseline. In the
30 preferred form, the acoustic monitor performs real-time
1/12th octave digital bandpass filtering over an eight
octave range (midband frequencies of 33.108 Hertz to 8,000
Hertz) and computes the acoustic power output, in decibels,
of each of the resulting 96 bandpass filters. Fractional
35 octave bandpass filtering produces a constant percentage
bandwidth analysis, that is, the bandwidth of each bandpass
filter is a constant percentage of its midband frequency.

-5-

1 In the case of a 1/12th octave bandpass filter, the
bandwidth is always 5.78 percent of the midband frequency.
This type of spectrum analysis is widely used in the field
of acoustics, as opposed to the constant bandwidth FFT
5 analysis preferred for vibration measurements. In terms of
signal processing, the acoustic monitor according to the
teachings of the present invention functions in exactly the
same way as an instrument known as a digital filter
analyzer. The digital filters conform to American National
10 Standard S1.11 - 1986 "Specification for Octave-Band and
Fractional-Octave-Band Analog and Digital Filters". The
use of digital filters in the acoustic monitor according to
the teachings of the present invention, as opposed to analog
filters, is highly desirable for three reasons: (1) Analog
15 implementation of the 96 bandpass filters described herein
would require a very large number of precision resistors,
capacitors, and operational amplifiers, (2) Component aging
and drift would cause the filter characteristics to change
over time and temperature, and (3) It is easy to control,
20 simulate, and modify, if necessary, the characteristics of
digital filters implemented in software.

The acoustic monitor according to the teachings of the
present invention has two modes of operation: learn and
operate. Before protection can be provided, the monitor
25 must be placed in a learn mode for a period of time so it
can "learn" what the sound source sounds like when the sound
source is known to be operating properly. The monitor can
remain in the learn mode for a few minutes, several hours,
or even days, but it must be a long enough time for the
30 acoustic monitor to experience all of the sounds which
normally occur in the environment in which the sound source
is located. During the learn mode, the maximum and minimum
acoustic power output from each one of the 96 bandpass
filters is continuously maintained and updated in data memory
35 as the acoustic signature of the sound source being monitored.
In this manner, the alarm limits are automatically
established, without requiring the judgment and experience

-6-

1 of a skilled operator. A copy of the acoustic signature is
also maintained in non-volatile memory (NVM) which preserves
the data whenever the acoustic monitor is powered down.
While in the learn mode, the acoustic signature is written
5 to NVM every ten minutes. It is also written to NVM
whenever the front panel mode switch is changed from LEARN
to OPERATE. The NVM copy of the acoustic signature cannot
be continuously updated because the electrically erasable
programmable read-only memory (EEPROM) used for this purpose
10 in the preferred form typically has an endurance of no more
than one million write cycles. Thus, an electrical power
interruption during the learn mode would cause, at most, ten
minutes of data to be lost. Operator intervention is
required to continue in the learn mode after power is
15 restored. This is to prevent the acoustic monitor from
powering up unexpectedly in the learn mode and corrupting an
acoustic signature which is already stored in NVM.

During the operate mode, the acoustic monitor of the
preferred form of the present invention continuously
20 compares the real-time filter outputs with the acoustic
signature previously stored during the learn mode and
activates a panel lamp and relay if the output of any of the
96 bandpass filters deviates from the upper or lower decibel
limits of the acoustic signature by more than the setting of
25 the corresponding front panel sensitivity selector switch.
There are two alarm settings: warning and danger. The
warning and danger levels, in decibels, can be set
independently and can be individually configured for either
latching or non-latching alarm operation, using front panel
30 switches. A latching alarm remains active until the clear
button is pressed or a valid signal is received at the
remote clear terminal, even if the machinery or similar
sound source returns to normal operation. A non-latching
alarm is automatically deactivated if the machinery or
35 similar sound source returns to normal. During non-latching
operation, both alarms employ hysteresis to prevent relay
chatter when slowly changing sounds are encountered.

-7-

1 In the preferred form, the acoustic power output of each
bandpass filter is computed by squaring its output and
time-averaging the result, because the energy in a wave is
proportional to the square of its amplitude. The response
5 time of the averaging filters can be adjusted from 1 to 1000
seconds, using a front panel selector switch. The response
time is defined as the time required for the filter outputs
to settle to within one percent of their final value after a
step change in acoustic power. Note that this is not
10 necessarily equal to the length of time it takes for the
acoustic monitor to respond to an operating condition fault.
It is merely another way of specifying the transient
response of a first-order system (response time = 4.605 time
constants). Selecting the appropriate response time for the
15 application will enable the acoustic monitor to respond to
an operating condition fault within a reasonable length of
time, while ignoring short-term background noise events.

The acoustic monitor according to the teachings of the
present invention allows the user to record and utilize up
20 to five acoustic signatures. This multiple acoustic
signature capability is designed for monitoring applications
that involve more than one acoustical "phase of operation".
That is, the sound radiating from a sound source may not be
continuous in nature, but may be characterized as having
25 several distinct regions of operation, each having its own
acoustic signature. For example, an automated test stand
which uses sound to detect product defects could perform up
to five types of tests, each producing a different acoustic
signature. However, the acoustic monitor cannot
30 automatically recognize which test is being performed or
what phase of operation a sound source is engaged in
because, without additional information, the acoustic
monitor could interpret the normal sound during one phase of
operation as an abnormal condition of another phase of
35 operation. During the operate mode, the acoustic monitor
must receive a command from either an operator or a host
controller, such as a programmable logic controller (PLC),

-8-

1 to change acoustic signatures. The command can be given .
manually, using the front panel clear button, or by a host
controller which sends an appropriately timed pulse through
the monitor's remote clear terminal.

5 During both the learn and operate modes, the acoustic
monitor according to the teachings of the present invention
continuously computes the real-time power spectrum of the
sound sensed by the microphone. The power spectrum of a
signal is valuable information that is widely used in the
10 field of acoustics, and the ability to view it in real time
represents a powerful capability which traditionally has
been very expensive. The acoustic monitor according to the
teachings of the present invention has terminals which allow
the user to view a graphical display of the following
15 important data with the aid of an ordinary oscilloscope:
(1) The real-time power spectrum of the acoustic signal, (2)
The upper decibel limit of the stored acoustic signature,
and (3) The lower decibel limit of the stored acoustic
signature. A trigger signal is also provided by the
20 acoustic monitor to facilitate external triggering of the
oscilloscope. In each case, the display is in the form of a
step graph which simultaneously shows the time-averaged
acoustic power outputs of all 96 digital bandpass filters
used to measure the power spectrum of the signal. Even the
25 most basic oscilloscope has two channels, allowing
simultaneous display of the upper and lower decibel (dB)
limits which constitute the acoustic signature. All three
graphical displays incorporate horizontal (time) and
vertical (voltage) markers which allow the user to easily
30 adjust out any inaccuracies in oscilloscope calibration.
The horizontal scale is calibrated in octaves (a logarithmic
measure of frequency) and the vertical scale is calibrated
in decibels (a logarithmic measure of acoustic power),
consistent with practices in the field of acoustics.

35 In its preferred form, the acoustic monitor according to
the teachings of the present invention consists of two
components: the control unit and the microphone unit. The

-9-

1 control unit contains the power supply, digital signal
processor, EPROM boot memory, non-volatile memory, A/D
converter, D/A converter, lamp/relay driver, switches,
indicator lamps, relays, and screw terminals, packaged in a
5 DIN rail-mountable enclosure which meets international
safety standards. There are relay outputs that can be
connected to an annunciator panel and others that can be
used to control the machinery or process being monitored.
The microphone unit contains a microphone, along with analog
10 signal conditioning circuitry, housed in a compact, rugged
enclosure suitable for use in an industrial environment.
The control unit and microphone unit are connected by a
4-conductor shielded cable which supplies DC power to the
signal conditioning circuitry inside the microphone unit,
15 while sending the amplified microphone signal in
differential form back to the control unit for digital
processing. This configuration yields the maximum
signal-to-noise ratio in electrically noisy industrial
environments.

20 A main object of the invention is to provide a new and
improved acoustic monitor for monitoring and evaluating
sounds emitted by a sound source wherein the acoustic
monitor is the type which computes the spectrum of the
monitored sound, and wherein the acoustic monitor has a
25 learning mode wherein a sound spectrum of a monitored sound
source is computed and stored as a signature spectrum and
has an operating mode wherein the sound spectrum of a
monitored sound source is computed continuously and compared
with the stored signature spectrum, and any deviations
30 therefrom of predetermined values are taken note of as a
basis for possible corrective action.

This and further objects and advantages of the
present invention will become clearer in light of the
following detailed description of an illustrative
35 embodiment of this invention described in connection
with the drawings.

-10-

DESCRIPTION OF THE DRAWINGS

The preferred embodiment of the invention may best be described by reference to the accompanying drawings where:

FIG. 1 is a functional block diagram showing the major hardware elements of the acoustic monitor, including a control unit which contains a power supply, digital signal processor, boot memory, non-volatile data memory, A/D converter, quad D/A converter, relay outputs, indicator lamps, and front panel switches; and a microphone unit which contains a microphone and signal conditioning electronics.

FIG. 2 is an illustration of the front panel of the control unit of the acoustic monitor of Figure 1 showing indicator lamps, user-operated switches, and screw terminals for user-installed wiring.

FIG. 3 is a graph showing the upper and lower decibel limits of the acoustic signature, the warning alarm limits, the danger alarm limits, and the real-time power spectrum of sound emitted from a sound source during the operate mode.

FIG. 4 is a digital signal-flow diagram which illustrates the operation of the learn and operate modes of the acoustic monitor of Figure 1 by tracing the route taken by digital samples as they move from the bandpass filter outputs, through the various stages of arithmetic processing, comparison, storage, and retrieval, before actuating the front panel indicator lamps and relay outputs.

All figures are drawn for ease of explanation of the basic teachings of the present invention only; the extensions of the figures with respect to number, position, relationship, and dimensions of the parts to form the preferred embodiment will be explained or will be within the skill of the art after the following description has been read and understood. Further, the exact dimensions and dimensional proportions to conform to specific force, weight, strength, and similar requirements will likewise be within the skill of the art after the following description has been read and understood.

Where used in the various figures of the drawings,

-11-

1 the same numerals designate the same or similar parts.
Furthermore, when the terms "first", "second", "front",
"upper", "lower", and similar terms are used herein, it
should be understood that these terms have reference only to
5 the structure shown in the drawings as it would appear to a
person viewing the drawings and are utilized only to
facilitate describing the illustrative embodiment.

DETAILED DESCRIPTION OF THE INVENTION

An electronic acoustic monitor for continuously
10 monitoring sound produced by and emanating from a sound
source for detecting abnormalities and thus determining
the operating condition of the sound source according to the
preferred teachings of the present invention is shown in the
drawings. The sound source could include but is not limited
15 to rotating machinery, non-rotating equipment, industrial
processes, and environments.

Referring to FIG. 1, a preferred embodiment of the
monitor according to the preferred teachings of the present
invention is shown including a control unit 10 and a remote
20 microphone unit 12 connected together by a 4-conductor
shielded cable 14 which in the most preferred form consists
of two individually shielded twisted pairs with a common
drain wire. Generally, control unit 10 contains a DC power
supply 16, a digital signal processor 18, a read-only boot
25 memory 20, a non-volatile data memory 22, an
analog-to-digital converter 24, a quad digital-to-analog
converter 26, relay outputs 30, front panel indicator lamps
32, and front panel switches 34.

In the preferred form, power supply 16 is a
30 high-efficiency linear power supply which receives
electrical power from the AC mains and produces a 5 volt DC
output for use by both analog and digital circuitry. The AC
input voltage in the most preferred form is
switch-selectable to accommodate either 100-130 VAC or
35 200-260 VAC operation. The primary and secondary windings
of the VDE-approved power transformer are fused and the dual

-12-

1 primary windings are protected against differential mode .
voltage transients by metal-oxide varistors. The
transformer employs an insulating shroud between the primary
and secondary windings to provide excellent isolation and
5 protection against common mode voltage transients. The
full-wave bridge rectifier circuit employs Schottky barrier
rectifiers to achieve the highest possible transformer
utilization. The bridge rectifier output is filtered by a
capacitor and fed to a low-dropout linear voltage regulator.
10 The 5 volt regulated DC output is distributed to the
circuitry using separate analog and digital power and ground
planes on the processor circuit board.

In the preferred form, digital signal processor 18 is a
25 MHz ADSP-2101 DSP microcomputer manufactured by Analog
15 Devices, Inc. Processor 18 is a 16-bit, fixed-point,
single-chip microcomputer optimized for DSP applications.
When coming out of a valid reset condition, processor 18
copies machine language instructions from boot memory 20 to
its on-chip program memory. After all of the instructions
20 have been copied, processor 18 begins executing the
instructions now residing in its program memory. Boot
memory 20 is connected to processor 18 and in the preferred
form is an industry-standard 27C128 16Kx8 CMOS EPROM in
either a one-time programmable or UV-erasable package.

25 Non-volatile data memory 22 can be read and written by
processor 18 and in the preferred form is an
industry-standard, four-wire serial interface 16,384-bit
93C86A CMOS EEPROM configured as 1,024 words x 16 bits. Its
function is to maintain a copy of the acoustic signature
30 whenever the monitor is powered down.

Analog-to-digital converter 24 receives an analog signal
from remote microphone unit 12 and outputs digital data to
processor 18. Converter 24 in the preferred form is a
16-bit sigma-delta type of converter having differential
35 voltage inputs and a serial data output compatible with the
serial port of processor 18. This type of A/D converter has
several inherent characteristics which can be advantageously

-13-

1 employed by the present invention: (1) The differential
analog inputs provide rejection of common-mode noise that
may be capacitively or inductively coupled to cable 14 in an
electrically noisy industrial environment, (2) The analog
5 input is continuously oversampled at a very high rate by an
analog modulator, thus eliminating the need for external
sample-and-hold circuitry, (3) The modulator output is
processed by two finite impulse response (FIR) digital
filters in series, greatly reducing the complexity of the
10 external anti-aliasing filter, and (4) The sample rate,
digital filter corner frequency, and output word rate are
proportional to the frequency of the clock signal supplied
to A/D converter 24 by digital signal processor 18.

Quad digital-to-analog converter 26 receives digital
15 data from processor 18 and outputs analog signals to an
optional oscilloscope 28. In the preferred form, converter
26 consists of four individual 10-bit D/A converters which
receive data from the serial port of processor 18 and which
produce analog voltage outputs timed to generate graphical
20 displays of data on optional oscilloscope 28. The four
digital-to-analog converter (DAC) channels generate the
following analog signals, available at the front panel screw
terminals: (1) The real-time power spectrum of the acoustic
signal, (2) The upper decibel limit of the stored acoustic
25 signature, (3) The lower decibel limit of the stored
acoustic signature, and (4) A trigger signal to facilitate
external triggering of oscilloscope 28. After data has been
written to the DAC registers, all four DAC outputs are
updated simultaneously, thus assuring vertical alignment of
30 the data displays on the screen of oscilloscope 28.

Relay outputs 30 can remotely signal the condition of
the machine or process being monitored and also provide
automatic shut-down, with lamps 32 showing the state of relay
outputs 30. Panel switches 34 configure the acoustic
35 monitor and control its operation.

Remote microphone unit 12 houses microphone 36 and
analog signal conditioning circuitry 38 in a compact, heavy

-14-

1 duty enclosure suitable for use in an industrial
environment. In the preferred form, microphone 36 is of the
electret condenser type, packaged in a rugged stainless
steel housing with a sintered stainless steel sound port
5 treated with water repellent. This particular microphone is
designed to withstand severe temperature and humidity
conditions, and it has a high resistance to mechanical
shock. Microphone 36 is mounted inside a resilient foam
windscreen which protects microphone 36 from dust and other
10 contaminants and which also helps to isolate microphone 36
from vibration. Microphone 36 is connected to the circuit
board containing signal conditioning circuitry 38 by means
of a shielded cable. The most flexible cable available is
used for this purpose to minimize the transmission of
15 vibration from the circuit board to microphone 36.

Electrical design, circuit board layout, grounding, and
shielding are critical factors in the design of microphone
unit 12 to minimize the introduction of electrical noise
into the analog signal path.

20 In the preferred form, signal conditioning circuitry 38
amplifies the very low-level, single-ended voltage generated
by microphone 36, converts the microphone voltage to a
differential voltage, and drives cable 14. The power pair
of cable 14 supplies remote microphone unit 12 with 5 volt
25 DC power from control unit 10. The signal pair of cable 14
transmits the differential analog signal back to control
unit 10 for digital processing. The voltage gain of signal
conditioning circuitry 38 can be adjusted from 0 to 100 by
means of a 25-turn trimming potentiometer, located on the
30 circuit board in remote microphone unit 12. The following
techniques have been employed to maximize the
signal-to-noise ratio of the analog signal path: (1) Place
all of the required amplification physically as close as
possible to microphone 36, (2) Transmit the analog signal as
35 a differential voltage to provide rejection of common-mode
electrical noise that may be capacitively or inductively
coupled to cable 14, (3) Use shielded cable to protect the

-15-

1 signal conductors from capacitively coupled (electric field)
interference, and (4) Use twisted-pair cable to reduce
inductively coupled (magnetic field) interference by
reducing the net loop area of the signal conductors. In
5 practice, remote microphone unit 12 should be rigidly
mounted in close proximity to the sound source being
monitored to minimize background acoustical noise pickup.
All of the above measures have the effect of reducing the
noise floor, and therefore increasing the dynamic range, of
10 the acoustic monitor.

The function of relay outputs 30, front panel indicator
lamps 32, and front panel switches 34 can best be understood
by referring to FIG.2, which shows the preferred form of a
front panel of control unit 10. The acoustic monitor is
15 always in one of the following four possible states: OKAY,
WARNING, DANGER, and NOT READY. These states are signaled
to external devices, such as annunciator panels or machinery
controls, by relay outputs 30 connected to the contacts of
three electromechanical relays: a SPDT OKAY relay, a SPDT
20 WARNING relay, and a DPDT DANGER relay. Relay outputs 30
are divided into two groups: five annunciator terminals
labeled COMMON, OKAY, WARNING, DANGER, and NOT READY; and
three control terminals labeled COMMON, NORMALLY OPEN
(N.O.), and NORMALLY CLOSED (N.C.). Only one of the relays
25 is actuated at a time, and the contacts are wired such that
the annunciator COMMON terminal makes contact with the OKAY,
WARNING, DANGER, or NOT READY terminal to signal the state
of control unit 10. In addition, the control COMMON
terminal makes contact with the control N.O. terminal
30 whenever control unit 10 is in the DANGER state; otherwise,
it makes contact with the control N.C. terminal. This
feature enables automatic shutdown of the sound source being
monitored if the acoustic monitor detects a dangerous
condition.

35 Front panel indicator lamps 32, shown collectively in
FIG. 1, are shown individually in FIG.2. In the most
preferred form, lamps 32 include green OKAY lamp 40, yellow

-16-

1 WARNING lamp 42, and red DANGER lamp 44 which are turned on
whenever the corresponding OKAY, WARNING, or DANGER relay is
energized. If none of these lamps is turned on, control
unit 10 is in the NOT READY state. Orange LEARN lamp 46 is
5 turned on whenever control unit 10 is in the learn mode.
Red FAULT lamp 48 flashes to indicate that the operator must
wait, or that the operator has made an error. FAULT lamp 48
is continuously lighted whenever control unit 10 detects a
hardware or software error. Control unit 10 tests itself at
10 power-up and continuously during operation.

Front panel switches 34, shown collectively in FIG. 1,
are shown in greater detail in FIG.2. In the most preferred
form, switches 34 include a POWER switch 50 which turns the
5 volt power supply on and off; a MODE switch 52 which
15 selects either the learn or operate mode; ALARM FUNCTION
switches 54 and 56 which select either latching or
non-latching operation of the warning and danger alarms;
respectively; and a CLEAR button 58 which clears a latched
alarm condition, erases an existing acoustic signature, or
20 selects a different acoustic signature, depending on the
settings of the other switches and the length of time CLEAR
button 58 is held down. Switches 60, 62, and 64 are
10-position rotary selector switches. RESPONSE TIME
selector switch 60, calibrated in seconds, controls the
25 length of time it takes for the digital averaging filters to
respond to a sudden change in acoustic power. WARNING LEVEL
selector switch 62, calibrated in decibels, controls the
sensitivity of the warning alarm. DANGER LEVEL selector
switch 64, also calibrated in decibels, controls the
30 sensitivity of the danger alarm. Adjustable filter response
time and alarm sensitivity are essential to ensure that
operating condition faults are reliably detected and false
alarms are minimized.

Analog and digital signal flow through the acoustic
35 monitor begins at the sound source, such as where vibrating
machine elements cause pressure variations to propagate
through the surrounding air until they reach microphone unit

-17-

1 12, where they are converted to a corresponding variation in
voltage by microphone 36, amplified and converted to
differential form by analog signal conditioning circuitry
38, transmitted over cable 14 to control unit 10, filtered
5 by a lowpass anti-aliasing filter, sampled at regular
intervals and converted to digital form by analog-to-digital
converter 24, and then conveyed to the serial port of
digital signal processor 18 for spectral analysis by means
of a bank of 96 digital bandpass filters.

10 Digital filtering in digital signal processor 18 is
accomplished by three types of infinite impulse response
(IIR) filters, implemented in software using 16-bit
fixed-point arithmetic: (1) Twelve sixth-order 1/12th
octave Butterworth bandpass filters, (2) One eighth-order
15 inverse Chebyshev lowpass filter, and (3) One first-order
adjustable time constant averaging filter. The sixth-order
Butterworth bandpass filters are implemented by cascading
three second-order sections, with each section being
computed using the following difference equations:

20

$$\begin{aligned}y(n) &= B_0 x(n) + w_1(n-1) \\w_1(n) &= A_1 y(n) + w_2(n-1) \\w_2(n) &= A_2 y(n) - B_0 x(n)\end{aligned}$$

25 Similarly, the eighth-order inverse Chebyshev lowpass filter
is implemented by cascading four second-order sections, with
each section being computed from the following difference
equations:

30

$$\begin{aligned}y(n) &= B_0 x(n) + w_1(n-1) \\w_1(n) &= B_1 x(n) + A_1 y(n) + w_2(n-1) \\w_2(n) &= B_0 x(n) + A_2 y(n)\end{aligned}$$

In the above difference equations, the symbols are defined
35 as follows:

$$x(n) = \text{Filter Input}$$

-18-

1 $y(n)$ =Filter Output
 $w_1(n), w_2(n)$ =Storage Elements
 $w_1(n-1), w_2(n-1)$ =Previous Storage Elements
 A_1, A_2, B_0, B_1 =Filter Coefficients (Constants)

5

The filter coefficients which appear in the foregoing difference equations were computed using a commercially available software package intended for digital filter design, analysis, and simulation. Several such software
10 packages are on the market, and the utility and use of such software will be familiar to those who are skilled in the art.

The magnitude response of the digital filter, as a function of frequency expressed in Hertz, depends on the
15 sample rate of the data which is being processed by the filter. It is customary in the field of acoustics to work with a logarithmic frequency scale based on the octave, which denotes a frequency ratio of 2:1. Filters which operate in the highest frequency octave analyzed by digital
20 signal processor 18, known as the top octave, process samples received directly from analog-to-digital converter 24. For the top octave, the sample rate is equal to the output word rate of the A/D converter. To obtain the data for the next lower octave, the top octave samples first pass
25 through a digital anti-aliasing filter (eighth-order inverse Chebyshev lowpass filter). Then, using a process known as decimation, the sample rate is halved by discarding every other output sample. The decimated samples are then processed by the same 1/12th octave bandpass filters used in
30 the top octave. The digital anti-aliasing filter prevents high frequency components from being folded into the frequency range covered by the bandpass filters when the sample stream is decimated. This process of lowpass filtering, decimation, and bandpass filtering is repeated
35 until eight octaves have been analyzed. It can then be appreciated that it is not necessary to employ 96 distinct bandpass filters to provide 1/12th octave bandpass filtering

-19-

1 over an eight octave range. Only twelve bandpass filters
and one lowpass anti-aliasing filter are required because
the filters are identical for each octave; only the sample
rate changes.

5 In order to perform filtering in real time, over an
eight octave range, digital signal processor 18 must process
and store data for each octave in the proper sequence, while
new samples are continually received from analog-to-digital
converter 24. This is accomplished with eight
10 filter/decimator stages which operate in a continuous loop,
performing bandpass filtering for octaves 0 through 7, where
octave 0 is the lowest frequency octave and octave 7 is the
top octave. The first stage receives data from A/D
converter 24, performs the octave 7 bandpass filtering, and
15 produces band-limited input data for the second stage at a
sample rate which is one-half the output word rate of the
A/D converter. The second stage receives data from the
first stage, performs the octave 6 bandpass filtering, and
produces band-limited input data for the third stage at a
20 sample rate which is one-fourth the output word rate of the
A/D converter, and so on through the eighth stage of
filtering and decimation, which receives data from the
seventh stage at 1/128th the output word rate of the A/D
converter, and performs the octave 0 bandpass filtering (the
25 decimated samples from the eighth filter/decimator stage are
discarded).

Analog-to-digital converter 24 continuously samples the
differential analog signal received from remote microphone
unit 12 and converts the samples to signed (twos-complement)
30 16-bit data words. Each time the serial port of digital
signal processor 18 receives a data word from A/D converter
24, an interrupt is generated. All of the digital filtering
performed by digital signal processor 18 occurs in the
interrupt service routine associated with the serial port
35 receive interrupt. Octave 7 data must be processed every
time a data word is received by the serial port. Data for
one additional octave must also be processed during the same

-20-

1 interrupt, except for the last interrupt of every
 128-interrupt cycle. The filter/decimator sequence, that
 is, the order in which octaves 0 through 6 must be
 processed, is stored in a look-up table in the program
 5 memory of digital signal processor 18, and is as follows:

6,5,6,4,6,5,6,3,6,5,6,4,6,5,6,2,6,5,6,4,6,5,6,3,6,5,6,4,6,5,6,1,
 6,5,6,4,6,5,6,3,6,5,6,4,6,5,6,2,6,5,6,4,6,5,6,3,6,5,6,4,6,5,6,0,
 6,5,6,4,6,5,6,3,6,5,6,4,6,5,6,2,6,5,6,4,6,5,6,3,6,5,6,4,6,5,6,1,
 10 6,5,6,4,6,5,6,3,6,5,6,4,6,5,6,2,6,5,6,4,6,5,6,3,6,5,6,4,6,5,6,--

As can be seen from the above sequence, data for each octave
 is processed with the following frequencies:

15 Octave 7 - Every interrupt
 Octave 6 - Every 2nd interrupt
 Octave 5 - Every 4th interrupt
 Octave 4 - Every 8th interrupt
 Octave 3 - Every 16th interrupt
 20 Octave 2 - Every 32nd interrupt
 Octave 1 - Every 64th interrupt
 Octave 0 - Every 128th interrupt

The desired output from the digital filter analyzer just
 25 described is the time-averaged acoustic power output of each
 one of the 96 bandpass filters. To obtain this information,
 the output of each bandpass filter is first squared and then
 processed by a first-order averaging filter, implemented as
 follows:

30

$$y(n) = y(n-1) + K[x(n) - y(n-1)]$$

where the constant K depends on the position of RESPONSE TIME
 selector switch 60, and the octave which is being filtered.
 35 To a close approximation, K is equal to t/τ , where t is the
 sampling interval and τ is the time constant of the filter,
 both expressed in seconds. In the above equation, x(n) is

-21-

1 the filter input, $y(n)$ is the filter output, and $y(n-1)$ is the previous filter output.

Digital signal processor 18 further processes the 96 double-precision (32-bit) outputs from the foregoing averaging filter to obtain acoustic power on a logarithmic (decibel) scale for each one of the 96 filter bands required. It is customary to express acoustic power on a decibel (dB) scale because of the tremendous dynamic range of the human auditory system (120 dB). Due to the binary nature of digital signal processor 18, it is convenient to compute the base 2 logarithm of the filter output, rather than the customary natural (base e) or common (base 10) logarithms. Furthermore, digital signal processor 18 is optimized for performing calculations on numbers which are in a 16-bit signed (twos-complement) fractional format consisting of one sign bit (the most significant bit) followed by fifteen fractional bits. After squaring the bandpass filter output and smoothing the result with the averaging filter, the resulting time-averaged acoustic power is expressed as a 32-bit fractional number which is always positive. Therefore, on a logarithmic scale, the power output of each bandpass filter varies from a full-scale level of 0 dB (in the limiting case) down to the noise floor of the system, typically about -72 dB. The numerical representation of acoustic power in digital signal processor 18 is not absolute, in the sense that it does not represent a physical measurement having specific dimensions. A relative measure of acoustic power is all that is required for the purposes of the acoustic monitor according to the teachings of the present invention because it is the change in the power spectrum of sound emitted from the sound source that is indicative of failure, not the absolute spectrum. Comparing the real-time power spectrum with the baseline spectrum (the acoustic signature) is straightforward because, during the operate mode, the analog and digital signal path is the same as it was during the learn mode, when the baseline spectrum was recorded. Thus, unit-to-unit

-22-

1 variations in system gain and frequency response are canceled out.

The operation of the oscilloscope data viewing feature is best explained by referring to FIG. 3, which shows the
5 real-time power spectrum 66 of the monitored sound source, and the stored acoustic signature, consisting of an upper decibel limit 68 and a lower decibel limit 70. FIG. 3 is a graph showing essentially a magnified view of the screen of optional (multi-channel) oscilloscope 28 of FIG. 1 when
10 channels A, B, and C of quad digital-to-analog converter 26 are displayed simultaneously, while triggering oscilloscope 28 externally using the trigger signal from channel D. On the oscilloscope screen, the vertical scale is calibrated in decibels (20 dB/div) and covers a range from -80 dB to 0 dB.
15 The horizontal scale is calibrated in 1/12th octave bands (10 bands/div) over an eight octave range (9.6 divisions). The real-time acoustic power 66, the upper dB limit 68, and the lower dB limit 70, for each filter band, appear as horizontal steps on a 96-step graphical display. In FIG. 3,
20 twelve steps are shown for the top-octave filter bands, the other seven octaves having a similar appearance. The numbers on the x-axis (log frequency) represent the band edge frequencies, in Hertz, of the top-octave bandpass filters. The numbers on the y-axis (log power) represent
25 the relative acoustic power output, in decibels, of the top-octave bandpass filters.

The operation of the warning and danger alarms can be understood by again referring to FIG. 3, where a portion of upper decibel limit 68 has been displaced upward by an
30 amount equal to the setting of WARNING LEVEL selector switch 62 to create upper warning limit 68A, and lower decibel limit 70 has been displaced downward by an equal amount to create lower warning limit 70A. In a similar manner, a portion of upper decibel limit 68 has been displaced upward
35 by an amount equal to the setting of DANGER LEVEL selector switch 64 to create upper danger limit 68B, and lower decibel limit 70 has been displaced downward by an equal

-23-

1 amount to create lower danger limit 70B. Upper decibel
limit 68 and lower decibel limit 70 constitute the acoustic
signature of the monitored sound source, and represent the
range of acoustic power output observed during the learn
5 mode for each one of the 96 bandpass filters. Thus, it can
be seen that warning alarm limits 68A and 70A define an error
band for the warning alarm, with the sensitivity being
controlled by WARNING LEVEL selector switch 62, and that
danger alarm limits 68B and 70B define an error band for the
10 danger alarm, with the sensitivity being controlled by
DANGER LEVEL selector switch 64. For example, real-time
power spectrum 66 falls within warning alarm limits 68A and
70A, so no alarm is generated; however, real-time power
spectrum 66A falls outside warning alarm limit 68A, so the
15 warning alarm is activated.

The operation of the learn and operate modes, as well as
the warning and danger alarms, is further understood by
referring to the digital signal-flow diagram of FIG. 4.
This diagram shows the flow of digital samples for one of
20 the 96 filter bands and is presented in the form of an
electrical schematic, even though all of the operations
depicted in this diagram are implemented in software by
digital signal processor 18. For each filter band, samples
for the appropriate octave are first processed by
25 sixth-order 1/12th octave Butterworth bandpass filter 72,
squared by squarer 74, smoothed by first-order averaging
filter 76, and then converted to a decibel representation by
binary (base 2) logarithm converter 78. The response time,
and therefore the time constant, of first-order averaging
30 filter 76 is controlled by RESPONSE TIME selector switch 60.
The output of logarithm converter 78 is proportional to the
time-averaged acoustic power output, in decibels, of
bandpass filter 72. At this point, the signal path is
determined by MODE switch 52, which selects either the learn
35 mode (upper position) or the operate mode (lower position).
In the learn mode, the output of logarithm converter 78 is
continuously compared, on a sample-by-sample basis, with the

-24-

1 acoustic signature residing in random access memory (RAM) .
80 of digital signal processor 18. The upper decibel
limits, read from memory 80A, are processed in the upper
portion of the signal-flow diagram. The lower decibel
5 limits, read from memory 80B, are processed in the lower
portion of the signal-flow diagram. If already existing in
non-volatile memory (NVM) 22, a valid acoustic signature is
loaded into RAM 80 by digital signal processor 18 during
the operate mode, before entering the learn mode. In this
10 case, the learn mode will expand the upper and lower decibel
limits of the existing acoustic signature. If there is no
existing acoustic signature in NVM 22, the upper decibel
limits are initialized in memory 80A by initial conditions
82 and the lower decibel limits are initialized in memory
15 80B by initial conditions 84. Initial conditions 82
correspond to the minimum acoustic power (-80 dB) and
initial conditions 84 correspond to the maximum acoustic
power (0 dB). The upper decibel limits are determined by
comparator 86, working in a loop with memory 80A. Each time
20 a sample is received from logarithm converter 78, the sample
is compared by comparator 86 with the corresponding upper
decibel limit read from memory 80A. If the sample is
greater than the limit, comparator 86 overwrites the
existing limit with the value of the sample, thus
25 establishing a new upper decibel limit in memory 80A for the
filter band in question. In a similar manner, the lower
decibel limits are determined by comparator 88, working in a
loop with memory 80B. If the sample received from logarithm
converter 78 is less than the corresponding lower decibel
30 limit read from memory 80B, comparator 88 overwrites the
existing limit with the value of the sample, thus
establishing a new lower decibel limit in memory 80B for the
filter band in question. This process continues for as long
as MODE switch 52 is in the learn position. During the
35 learn mode, the acoustic signature stored in RAM 80 is
written to NVM 22 every ten minutes, and again when MODE
switch 52 is moved from the learn position to the operate

-25-

1 position.

When MODE switch 52 is in the operate position, the sample stream is directed from the output of logarithm converter 78 to the non-inverting inputs of comparators 98 and 100 and to the inverting inputs of comparators 102 and 104. Comparators 98, 100, 102, and 104 employ hysteresis to prevent oscillation when the output logic state changes. The reference level for comparator 98 is the sum of the WARNING LEVEL set by selector switch 62 and the corresponding upper decibel limit read from memory 80A, computed by summing unit 90. Comparator 98 turns on (outputs a logic 1) when the level at the non-inverting input reaches the reference level, and turns off (outputs a logic 0) when the level at the non-inverting input drops to a value equivalent to the arithmetic average of the upper decibel limit and the reference level. The reference level for comparator 100 is the sum of the DANGER LEVEL set by selector switch 64 and the corresponding upper decibel limit read from memory 80A, computed by summing unit 92. Comparator 100 turns on when the level at the non-inverting input reaches the reference level, and turns off when the level at the non-inverting input drops to a value equivalent to the arithmetic average of the warning and danger reference levels. The reference level for comparator 102 is equal to the lower decibel limit read from memory 80B minus the WARNING LEVEL set by selector switch 62, computed by subtraction unit 94. Comparator 102 turns on when the level at the inverting input drops below the reference level, and turns off when the level at the inverting input rises above a value equivalent to the arithmetic average of the lower decibel limit and the reference level. The reference level for comparator 104 is equal to the lower decibel limit read from memory 80B minus the DANGER LEVEL set by selector switch 64, computed by subtraction unit 96. Comparator 104 turns on when the level at the inverting input drops below the reference level, and turns off when the level at the inverting input rises above a value equivalent to the

-26-

1 arithmetic average of the warning and danger reference
levels.

The outputs of comparators 98 and 102 are connected to
the inputs of OR gate 108. Therefore, the output of OR gate
5 108 will be a logic 1 whenever the real-time acoustic power
output of any of the 96 bandpass filters deviates from the
upper or lower decibel limits of the acoustic signature by
an amount greater than the setting of WARNING LEVEL selector
switch 62. The output of OR gate 108 will remain at a logic
10 1 until the maximum power deviation drops below one-half the
setting of WARNING LEVEL selector switch 62.

The outputs of comparators 100 and 104 are connected to
the inputs of OR gate 106. Therefore, the output of OR gate
106 will be a logic 1 whenever the real-time acoustic power
15 output of any of the 96 bandpass filters deviates from the
upper or lower decibel limits of the acoustic signature by
an amount greater than the setting of DANGER LEVEL selector
switch 64. The output of OR gate 106 will remain at a logic
1 until the maximum power deviation drops below the
20 arithmetic average of the settings of WARNING LEVEL selector
switch 62 and DANGER LEVEL selector switch 64.

In the preferred form, digital signal processor 18 is
programmed to flash red FAULT lamp 48 continuously at a 1
Hertz rate and suspend normal operation of the acoustic
25 monitor, unless the setting of DANGER LEVEL selector switch
64 is greater than the setting of WARNING LEVEL selector
switch 62. Therefore, if the output of OR gate 106 is a
logic 1, the output of OR gate 108 will also be a logic 1.
The output of OR gate 108 is gated by AND gate 110 in such a
30 manner that the output of AND gate 110 cannot equal a logic
1 unless the output of OR gate 106 is a logic 0. The output
of AND gate 112, with inverted inputs, will be equal to a
logic 1 only if the outputs of OR gates 106 and 108 are both
equal to logic 0. Therefore, the output of AND gate 112
35 will be a logic 1 if control unit 10 is in the OKAY state,
the output of AND gate 110 will be a logic 1 in the WARNING
state, and the output of OR gate 106 will be a logic 1 in

-27-

1 the DANGER state. Only one of these three outputs can be a
logic 1, since control unit 10 can only be in one state at a
time. These logic signals are further gated by AND gates
114, 116, and 118 in such a manner that the outputs of AND
5 gates 114, 116, and 118 cannot equal logic 1, unless MODE
switch 52 is in the operate position. When the output of
AND gate 118 is a logic 1, green OKAY lamp 40 is turned on
and OKAY relay 120 is actuated. When the output of AND gate
116 is a logic 1, yellow WARNING lamp 42 is turned on and
10 WARNING relay 122 is actuated. When the output of AND gate
114 is a logic 1, red DANGER lamp 44 is turned on and DANGER
relay 124 is actuated. When MODE switch 52 is in the learn
position, front panel indicator lamps 40, 42, and 44 are
turned off, relays 120, 122, and 124 are deactivated, and
15 orange LEARN lamp 46 is turned on.

Relay outputs 30, shown collectively in FIG. 1 and FIG.
4, are shown individually in FIG. 2, along with the other
recessed screw terminals intended for user-installed wiring.
Terminals 126 (Line) and 128 (Neutral) are the AC power
20 input connections. A line voltage select switch for
selecting either the 115 or 230 VAC nominal line voltage is
on the rear panel of control unit 10. In the preferred
form, relay outputs 30 include five annunciator terminals
130, 132, 134, 136, and 138, labeled Okay, Common, Warning,
25 Not Ready, and Danger, respectively. Relay outputs 30 in
the preferred form further include three control terminals
140, 142, and 144, labeled N.O. (Normally Open), Common, and
N.C. (Normally Closed), respectively. Terminal 146 is the
Earth (Protective) Ground. Optional oscilloscope 28 is
30 connected to terminals 148, 150, 152, and 154, labeled Power
Spectrum, Upper dB Limits, Lower dB Limits, and Scope
Trigger, respectively. Terminal 156, labeled Clear, accepts
a 5-30 volt DC signal and performs the same function as
front panel CLEAR button 58. Four-conductor shielded cable
35 14, coming from remote microphone unit 12, connects to
terminals 158, 160, 162, and 164, labeled Analog +5V, Analog
Ground, Microphone (-), and Microphone (+), respectively.

-28-

1 The ground lead of optional oscilloscope 28 is connected to
analog ground terminal 160, the quietest ground point on
control unit 10, as is the drain wire of cable 14..

Thus since the invention disclosed herein may be
5 embodied in other specific forms without departing from
the spirit or general characteristics thereof, some of
which forms have been indicated, the embodiments
described herein are to be considered in all respects
illustrative and not restrictive. The scope of the
10 invention is to be indicated by the appended claims,
rather than by the foregoing description, and all changes
which come within the meaning and range of equivalency of
the claims are intended to be embraced therein.

-29-

CLAIMS

1. An electronic monitor for continuously monitoring sound produced by and emanating from a remotely located sound source such as rotating machinery, non-rotating equipment and industrial processes and environments for detecting abnormalities and thus determining the operating condition thereof, comprising, in combination: sensor means for detecting the sound emanating from the sound source comprising microphone means strategically locatable in proximity to the sound source for generating a signal; analog signal means for conditioning the signal generated by the microphone means and converting the signal to a differential analog signal; a control unit; cable means for supplying the analog signal conditioning means with DC power and conveying the differential analog signal from the analog signal conditioning means to the control unit for digital processing; analog-to-digital converter means for sampling the differential analog signal at regular intervals and converting the differential analog signal to a digital sample stream; digital filter means for continuously processing the digital sample stream to obtain the real-time power spectrum of the sound emanating from the sound source; memory means; learning mode means including means for calculating and storing in the memory means an acoustic signature copy of the power spectrum developed during a time when the sound source is known to be operating normally without any known disabilities; upper and lower dB warning limits relative to the acoustic signature copy having predetermined magnitudes which may be indicative of levels of undesired deterioration of the sound source; comparator means and warning means; and operating mode means including means for continuously calculating test copies of the power spectrum during the subsequent operation of the sound source and making respective comparisons of the test copies via the comparator means with the upper and lower dB limits and issuing warnings via the warning means upon the upper and

-30-

lower dB limits being reached.

2. A monitor according to claim 1 wherein the analog-to-digital converter means samples the differential analog signal for a sufficient time for the sensor to experience all of the relevant sounds emanated by the sound source.

3. A monitor according to claim 1 having learning and operating modes associated with the learning and operating mode means; and wherein the memory means includes RAM means cooperable with the comparator means during the learning and operating modes.

4. A monitor according to claim 3 wherein the memory means includes non-volatile data memory for storing multiple acoustic signatures and being cooperable with the RAM means.

5. A monitor according to claim 1 wherein the digital filter means comprises bandpass type filter means.

6. A monitor according to claim 1 wherein the cable means comprise a cable having two individually shielded twisted pairs with a common drain wire.

7. A monitor according to claim 1 wherein the sound source comprises rotating machinery, non-rotating equipment and other sound producing processes.

8. A monitor according to claim 1 including upper and lower dB danger limits having predetermined magnitudes which may be indicative of dangerous operating conditions.

9. A monitor according to claim 1 including a microcomputer programmed to perform the function of the digital filter means.

10. A monitor according to claim 9 wherein the microcomputer is further programmed to perform the function of the learning mode means and the operating mode means.

11. A monitor according to claim 10 wherein the microcomputer is further programmed to compute the upper and lower dB warning limits and to perform the functions of the comparator means and the warning means.

12. A monitor according to claim 11 wherein the

-31-

microcomputer is a digital signal processor.

13. A monitor according to claim 2 wherein the learning mode means may be utilized to sequentially calculate and store a plurality of acoustic signature copies for use in monitoring different operating conditions of the sound source.

14. A monitor according to claim 13 wherein the plurality of acoustic signature copies are stored in non-volatile data memory.

15. A monitor according to claim 2 wherein the operating mode means is operable in real-time.

16. A monitor according to claim 5 wherein the bandpass type filter means perform real-time 1/12th octave digital bandpass filtering over an eight octave range.

17. A monitor according to claim 16 wherein the bandpass type filter means compute the acoustic power output in decibels of each of 96 resulting bandpass filters.

18. A monitor according to claim 17 wherein the acoustic power of each of the bandpass filters is computed by squaring the output of the bandpass filters and averaging the result.

19. A monitor according to claim 2 wherein the learning mode means is selectively operable over a period from a few minutes to several days.

20. A monitor according to claim 2 including manual control means for alternately selecting the learning mode means and the operating mode means.

21. A monitor for continuously monitoring sound produced by and emanating from a remotely located sound source such as rotating machinery, non-rotating equipment and industrial processes and environments for detecting abnormalities and thus determining the operating condition thereof, comprising, in combination: sensor means for detecting the sound emanating from the sound source comprising microphone means strategically locatable in proximity to the sound source for generating a signal;

-32-

analog signal means for conditioning the signal generated by the microphone means and converting the signal to a differential analog signal; a control unit; cable means for supplying the analog signal conditioning means with DC power and conveying the differential analog signal from the analog signal conditioning means to the control unit for digital processing; analog-to-digital converter means for sampling the differential analog signal at regular intervals and converting the differential analog signal to a digital sample stream; digital filter means for continuously processing the digital sample stream to obtain the real-time power spectrum of the sound emanating from the sound source; memory means; learning mode means for respectively accessing and processing the digital sample stream to derive an acoustic signature copy of the power spectrum developed during a time when the sound source is known to be operating normally without any known disabilities; operating mode means for computing upper and lower dB limit values relative to the acoustic signature copy by respectively adding and subtracting predetermined values to and from the acoustic signature copy which may be indicative of an abnormality in the operating condition of the sound source, with the operating mode means including comparator means for accessing the digital sample stream and sequentially calculating test copies of the power spectrum during the subsequent operation of the sound source and making respective comparisons of the test copies via the comparator means with the upper and lower dB limit values and issuing alarm signals upon any of the limit values being reached; and switch means for selectively choosing the learning and operating modes.

22. A monitor according to claim 21 wherein the learning mode means is utilized to derive and store more than one acoustic signature copy corresponding to more than one sound source.

23. A monitor according to claim 21 wherein the upper

-33-

and lower dB limit values comprise first and second sets of limit values with each set straddling the acoustic signature copy, with the first set being a warning limit set which signifies a developing fault and the second set being a danger limit set which signifies a situation which requires immediate corrective action.

24. A monitor according to claim 23 wherein the comparator means includes first and second units operable relative to the first and second sets of limit values.

25. A monitor according to claim 24 including separate switch means for enabling the first and second units of the comparator means.

26. A monitor according to claim 24 having warning and danger signal output means connected to the first and second units of the comparator means.

INTERNATIONAL SEARCH REPORT

International Application No

PCT/US 99/16016

A. CLASSIFICATION OF SUBJECT MATTER
IPC 7 G01M7/02

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 G01M G01N

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	EP 0 371 631 A (GP TAURIO INC) 6 June 1990 (1990-06-06) claims 1-28 ---	1,21
Y	US 5 521 840 A (BEDNAR FRED H) 28 May 1996 (1996-05-28) column 4 -column 9 ---	1,21
A	US 5 686 652 A (PFUND BRUCE) 11 November 1997 (1997-11-11) column 4 -column 11 ---	1-26
A	US 4 052 889 A (MUCCIARDI ANTHONY N ET AL) 11 October 1977 (1977-10-11) claims 1-24 --- -/--	1-26

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex

Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"Z" document member of the same patent family

Date of the actual completion of the international search

26 October 1999

Date of mailing of the international search report

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ BLACK BORDERS
- ☐ IMAGE CUT OFF AT TOP, BOTTOM OR SIDES
- ☐ FADED TEXT OR DRAWING
- ☒ BLURRED OR ILLEGIBLE TEXT OR DRAWING
- ☐ SKEWED/SLANTED IMAGES
- ☐ COLOR OR BLACK AND WHITE PHOTOGRAPHS
- ☐ GRAY SCALE DOCUMENTS
- ☐ LINES OR MARKS ON ORIGINAL DOCUMENT
- ☐ REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY
- ☐ OTHER: _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
